

Morrow

A merchant-side commitment layer for a world where AI agents become first-class customers.

THE PROBLEM

Agents can reserve scarce tables, appointments, tickets, rentals, or stock at machine speed while intending to complete only one purchase. The merchant carries the cost of that uncertainty.

THE SOLUTION

The merchant exposes a paid, time-boxed commitment through an agent-readable API. It is non-refundable if it expires and credited in full when exercised on time. This gives scarce inventory an explicit price and state transition.

60-SECOND PROOF

Two buyer agents accept the same 0.20 XSGD x402 terms for one final merchant slot. The merchant selects one inventory winner. Only the winner advances to settlement; the loser pays S\$0. The winner receives a machine-readable commitment receipt and exercises it into a booking with full credit.

WHY IT FITS

TRACK 3

A new merchant API, policy, inventory decision, and receipt designed for autonomous customers.

STRAITSX

The commitment is priced in SGD-denominated XSGD: 200000 atomic units = 0.20 XSGD.

AVALANCHE + x402

Exact payment terms target XSGD on Avalanche C-Chain mainnet (eip155:43114).

AWS

The production architecture can use atomic inventory writes, queues, signing, and monitoring. The MVP makes no AWS deployment claim.

WHAT EXISTS NOW

A polished deterministic Vercel proof, agent capability endpoints, exact mainnet asset metadata, the winner/loser race, and a demo receipt.

HONEST BOUNDARY

The preview never accepts or broadcasts a wallet authorization. Facilitator compatibility and one funded mainnet transaction remain the live settlement gate.

NOT ONLY RESTAURANTS / clinic appointments / ticket allotments / equipment rentals / limited inventory
